

Whiley Comparison

Vivian Stewart

February 16, 2016

Abstract

1 Introduction

From an undergraduate perspective one might approach verification with optimism, some quite lofty aspirations might be assumed to be reasonable. However the truth of Software Verification is in actuality much more of a field of research with a limited level of user interaction in the tools tools and a fairly steep learning curve. Current efforts are impressive from an academic stand point, but require years of invested effort to learn the various analyses and how these fit together to prove correctness of program execution. This study touches on a small set of uses in this area, notably those dealing with the manipulation and searching of arrays of integers to mirror the way a C programmer might approach these problems. Several verification tools were chosen based on their ease of assimilation to the programming problems. The results show how the tools faired when given these simple programming problems with some background about their evolution and relative skill set needed by the programmer to prove correctness of these programs.

There are some interesting tools that have been developed recently, making for an easier more tractable learning curve and easing the burden of proof for the programmers whom may be a bit intimidated by formal specification or those who found other tools too much effort for meagre results. Specifications being a set of annotations stated before a function body and before a loop body to formally define what are the expected inputs, relative behaviour and results of function or loop execution.

As programmers we need some tools to assure us that, the code we have constructed, does exactly what we think it does. There are linter's, Unit testing, Static Analysis tools, all of which will give you some idea about some aspect of code execution but Formal Verification promises to cover all execution paths and test a specification with formal exacting precision. First Order Logic is expressed, as annotations, alongside actual program code to describe program execution which is then converted into verification conditions to be checked and asserted by an automated proof assistant. It is possible to completely or partially specify a program depending on critical importance of correctness and impact of failure, although complete specification is difficult to gauge and often not necessary.

Formal Logic is at first difficult to grasp for the majority of programmers and even the tools discussed here in require some background in Mathematical Logic, proof by contradiction, contrapositive and induction etc. Induction seems to be a tricky one not only for human beings

but for automated deduction as well, for instance, Z3 doesn't support induction (recursive) verification conditions, though there are structures available in Dafny for inductive proof, lemmas, functions, predicates (possibly in boogie?) One interesting learning step that caught me out was the order of statements in the specification was important which I thought unusual as one would tend to think of certain mathematical operations as commutative or associative and mathematical definitions as being declarative. But it would seem that logical operations in specifications employ short circuit logic which makes order of premises important. Pre- and post-conditions, loop invariants, assertions and framing.

2 Lessons learned

2.1 Transference

More often than not code made for one tool is easily transcribed to the other with little modification since there are usually very similar constructs for defining specifications, in the limited scope in which this study was performed. The difference in range notation between the different tools is note worthy as in Dafny ranges can simply be seen mathematically $0 \leq x < \text{length}$, where as Whiley is `x in 0..length` and `Spec# x in (0:length)` or `x in (0..length - 1)`. In Whiley the `a..b` means mathematically $[a, b)$. In `Spec# (a:b)` means $[a, b)$ (half-open interval) but `(a..b)` means $[a, b]$ (closed interval, inclusive.) I personally prefer Dafny's way for it's clarity though the others are short and concise, but this is a matter of taste. Potentially confusing off by one errors can be hard to see.

Intuitively one has to establish a correspondence between any of the variables that change in the loop of a program...

2.2 Verification Coverage

Knowing if there has been enough specification or even a complete specification is not immediate and it is easy to come up with only a partial specification. Hence, it raises two main questions: how to be sure that our specification is complete, and how complete must a specification be. For the first question, one must reason on some model of the specified program. For the second question, no definitive answer is known. It depends on the context in which the specification is written and the kind of properties that must be established. The amount of specification required for a given function is very different when verifying a given property for a given application in which calls to the function always occur in a well-defined context and when specifying as a library function which should be callable in as many contexts as possible.

2.3 Overflow

Considering overflow of integer or floating point numbers was not necessary when programming with Whiley or Dafny, both have unbounded or mathematical, integers and reals as basic types, so, overflow is not possible (though heap overflow might be a concern but this is an internal issue.) Frma-C on the other hand distinguishes between `int` (bounded) and `integer` (unbounded) types (since ACSL has to reflect the C code being specified) resulting in the possibility for overflow within the specification and hence a lot of extra thought is needed. For instance the difference

between an `int` and `unsigned int` is that an `unsigned int` can be twice as large as can possibly be stored in an `int`. Exposing us to all of the corner cases and intricacies of the C type system.

2.4 Arrays

Array bounds checking is part of all the automated verification tools tested. One would expect this to be part of a static analysis tool, but in the context of verification this is necessary to always ensure correct execution and is therefore always checked. In Frama-C this is extremely cumbersome since arrays do not know their own bounds.

2.5 Termination

I first came across proof of termination in Dafny where the `decreasing` keyword is used to express some variables in iterative or recursive code reaching a state of termination. For instance, in a while/for loop where we use `i` to traverse some linear data structure, that is `data[i]` and we know that `i` increases toward the end of the array, we can express this as `decreasing max - i`. Similarly in Frama-C the same can be expressed as `loop variant max - i`. but this kind declaration is missing from Whiley and Spec#. Proof of termination can relax the specification of loop invariants, though the benchmarks in our comparison have no examples where this is necessary or applicable.

2.6 To null or not to null?

Dafny and Frama-C need to have in their specifications the requirement that i.e arrays are not null `requires array != \null`. where as Whiley and Spec# have null and non-null types. In whiley a type can be defined as `(null | int)` otherwise all types are non-null. In Spec# however a non-null type is denoted by a trailing exclamation mark. Conversion between null and non-null types was not a situation that encountered.

2.7 Relative invariants

Simplification and it's effects, time taken to verify translates into more/less verification conditions?

2.8 Ghost Code

Dafny and Frama-C have facilities to allow embedding of code in the specification, in the form of lemmas, pure functions and predicates. In Dafny, unlike method bodies, the body of a function is not forgotten during verification, and this allows functions to be used directly in annotations. Frama-C on the other hand uses behaviours, axioms, predicates, etc. to cover the more difficult to prove code requiring i.e counting or skipping over elements in the array.

2.9 Quantifiers

Most of the tools supply universal and existential quantifiers but Spec# has some extra tricks which provide some convenience to some difficult to prove cases:

- `sum { int k in (0:a.Length); a[k] };`
- `product { int k in (1..n); k };`
- `min { int k in (0:a.Length); a[k] };`
- `max { int k in (0:a.Length); a[k] };`
- `count { int k in (0:n); a[k] % 2 == 0 };`

2.10 Framing and mutation

in Frama-C, Dafny and Spec# to cover the modification of data outside the scope of the current block of code (side-effects) there are keywords for just this purpose. In Frama-C there is **assigns** clauses for function specifications and **loop assigns** for the loop specification in which case Frama-C makes no assumptions about any variables anywhere, being modified, it has to be explicitly stated, for instance **assigns \nothing** because without **assigns** clauses it is assumed that the code could modify everything. Where as Whiley, Dafny and Spec# can look at the code and assert what is being modified and take this into account. Dafny will not allow the modification of parameter variables (function inputs) unless a **modifies** clause says otherwise.

3 Benchmarks

Selected benchmarks were intended to be simple since the verification of large blocks of code are exponentially asymptotic in logical deduction and/or not decidable in the worst case. The benchmarks range from simple to reasonably complex. Some of them were exercises recommended by David Pearce, where as others were suggested by Lindsey Grooves. To begin with, the main Idea of this project was to create some small programs for use in lecture slides or as examples in tutorials.

3.1 palindrome

Scans through an array from the outer elements inwards to the centre, searching for a mismatch in values in which case returning false if there is such a mismatch and returning true if there is no such mismatch.

3.2 firstIndexOf

Finds the first index where the specified element is found in the given array of integers, searching through the array from the zero index in the positive direction. returns immediately the item is found, otherwise traverses the entire array then returns -1 to represent the absence of the value in the array.

3.3 lastIndexOf

Finds the last index where the specified element is found in the given array of integers, searching through the array from the the highest index in the negative direction. A lot like the firstIndexOf function in that the entire array is traversed if the value is not found but quits early if the value is found.

3.4 max

Searches the entire list in order to find and return the largest integer found. Accumulating the maximum value evaluated so far, as the algorithm traverses the array.

3.5 occurrences

Returns the number of times a given value is encountered while traversing the array.

3.6 strlen

The **strlen** function is intended to mirror the C function of the same name. It counts the number of characters in a string (array) of characters, having come to the end of the list when encountering a null character. The null character is usually denoted as `'\0'`, but since there is no char type currently available in Whiley, instead we have to use an abstraction of this data type. Ascii characters are bytes (8 bits) their range of values is between 0 and 255 inclusive and the null character is 0.

3.7 linearSearch

Much like the firstIndexOf function but iterates through a sorted list and can therefore quit early when the element matching the value is either found or the value is exceeded by the current element. Previous versions found an index of insertion into the sorted part of the array.

3.8 binarySearch

Using the divide and conquer method to find the index of an element in the given array matching the given value.

3.9 append

Adds a single element to the end of the array by making a new array that is one element larger than the original and copies the original array in order to the lower elements and inserting the given value in the last index.

3.10 remove

The remove function should remove the item at the given index from the given array of integers and return the resulting array otherwise unchanged. The resulting array is of course one element shorter in length. This is done by creating a new array one smaller in size and then copying across the elements before the given index directly, followed by copying across elements above the index to a position one index lower and overwriting the removed element.

3.11 copy

Copies a region of the source array into a same sized region of the destination.

3.12 displace

rotates a region of the array by one place forward

3.13 insert

This function should insert the item at the given index from the items array. The resulting array is of course one element longer in length.

3.14 insertionSort

...

4 Results & Discussion

the loop invariants tended to be reflected in the postconditions.

Z3 has no inductive proof mechanism and I suspect this is why Dafny has such a messy inductive definition syntax that I also suspect derives from boogie rather than Z3.

Whiley allows you to do more with less, minimal syntax but more expressive. (IMPORTANT!! flexible language constructs)...

Dafny has more complicated syntax to deal with memory management i.e pointers/references, lots to remember and coordinate.

The tools Dafny provides are for the development of proofs in a “top-down” manner, and which allow us to concentrate on the “architecture” of the proof. Unlike Frama-C.

With Frama-C in particular, it is a 2-valued logic with only total functions. Consequently, expressions are never “undefined”. Having only total functions implies that one can write terms such as $1/0$, or $*p$ when p is null.

Specifications in Frama-C can have implicit casts between C-types and Mathematical types (something to watch out for.) Weird:

- $5/3$ is 1 and $5 \% 3$ is 2;
- $(-5)/3$ is -1 and $(-5) \% 3$ is -2;
- $5/(-3)$ is -1 and $5 \% (-3)$ is 2;
- $(-5)/(-3)$ is 1 and $(-5) \% (-3)$ is -2.

Frama-C When no ‘assigns’ clauses are specified, the function is allowed to modify every visible variable.

Terminates It is possible to relax a particular function’s specification by providing a formula that describes the conditions in which the function is guaranteed to terminate.

Assertions when the analyzer is not able to determine that an assertion always holds, it may be able to produce a pre-condition for the function that would, if it was added to the function’s contract, ensure that the assertion was verified.

Overflow overflow is/must be handled.

```

1  inductive reachable{L} (list* root, list* node) {
2    case root_reachable{L}:
3      \forall list* root; reachable(root,root);
4    case next_reachable{L}: // L indicates a Label -> memory state
5      \forall list* root, *node;
6      \valid(root) ==> reachable(root -> next, node) ==>
7      reachable(root,node);

```

```

1  requires \valid(p) && \valid(q);
2  ensures *p <= *q; // pointers
3  behavior p_minimum:
4    assumes *p < *q;
5    ensures *p == \old(*p) && *q == \old(*q);
6  behavior q_minimum:
7    assumes *p >= *q;
8    ensures *p == \old(*q) && *q == \old(*p);
9  complete behaviors p_minimum, q_minimum;
10 disjoint behaviors p_minimum, q_minimum;

```

No verifier can tell you whether your code doesn’t work the according to the specification or the specification doesn’t describe what the code does, as this depends on the intention of the user/developer. Frama-C ACSL specification language lacks flexible language constructs, very cumbersome/specialised syntax.

All languages need different forms of verification and to different degrees. Sensitivity to approach to the problem.

4.1 Whiley

Whiley is very easy to use and shows promise as a tool to verify programs in such a way that the accompanying specification scales with complexity of the program to be verified. Whiley offers a simplified program and specification definition. However, Whiley's underlying prover needs some work to bring Whiley up to the level attained by other tools.

Arrays in Whiley are not reference or pointer types, there is no possibility of the array being null, also copying of an array is just a matter of assigning that array to a different variable, bypassing the issue of specifying array copying loops. Some basic arithmetic and region ranges seem to be difficult for the whiley constraint solver (WyCS.)

The documentation for Whiley is by far the best from a novice perspective. But there a lack of more advanced guidance, which seems like a research topic in itself.

4.2 Dafny

Dafny is a sophisticated tool/language for verification based on Microsofts' Z3 prover and Boogie with Monodevelop/Visual Studio. Though tests were performed on the command line to gain feedback from Dafny. Dafny can use pure functional code to help prove the correctness of imperative code for instance, only functions can used in specification unless qualified as 'function method'. These pure function definitions require very minimal specification in order to provide lemmas, axioms and other mathematical constructs to prove correct execution. One thing that struck me as odd was the use of short circuit logic in the specifications which implies a certain order to the specifications statements. Dafny doesn't require return statements in the usual way and defines a return variable(s) that is assigned to, and if necessary a 'return' can be called for early return from the call. Explicit and obvious reference to the returned variable was very convenient. All function/method parameters are immutable unless specified otherwise. Inside the specifications arrays are treated differently from other containers but are implicitly convertible to the built in sequence type if needed. Which allows for the very convenient syntax: `arr1[m..n] == arr2[m..n]` for an adjacent element comparison avoiding the need for long winded predicates. But not so convenient in that a sequence cannot be easily converted back to an array. Arrays are always possibly null in Dafny and the there are attempts in the specification language to mitigate the issue of reference aliasing and other such memory management quirks (modifies clause.) Unlike Whiley arrays are of reference type and need to be null checked.

4.3 Frama-C

When it comes to verifying C code Frama-C seems to be a current industry favourite. But I found the gtk user interface to be cumbersome and confusing. The ACSL language would appear to appeal more to an expert C programmer which I am not. Much expertise is needed to master Frama-C and every aspect and plugin have large manuals and tutorials available, all very heavy in detail. What I really wanted was a more general tool that would help point out where errors in my reasoning were evident. Frama-C offers only the vaguest of clues and errors in my reasoning are not always obvious. The issues of bounded types are dealt with up front and checked with the WP plugin through an RTE (runtime error) option that injects (over/under)flow checks. Specifications are meant to be written in a style that complements C and is analogous to C, even mirroring C conventions and C arithmetic. The lack of consolidation makes the various plugins difficult to integrate into a workflow. The ACSL specification language is

littered with predefined predicates and detailed set of proof tools such as user defined predicates, behaviours, inductive(recursive) functions and axioms etc. Arrays were a very sticky issue in Frama-C and involve proof of non-null and the validation of the range of indices and elements. For loop invariants, proof of termination is provided by the loop 'variant' key word, which is hard to see in amongst loop 'invariant' clauses in the same comment code block. Also there are assigns clauses that define the frame of modification for both the function and loop invariants (loop assigns.) since unlike other tools Frama-C has no knowledge of what has been modified in the function or inside the loop (side effects). Since the C language does not have formal semantics one should take the verification of C code with a grain of salt, horribly coded nonsense with undefined results can still be verified.

4.4 Spec#

Spec# having the same underlying workings as Dafny (a.k.a Boogie and Z3) if there are many differences between the two.

5 Appendix

```

1 function isPalindrome(int[] chars) -> (bool r)
2   ensures r <=> all { x in 0..|chars|
3     | chars[x] == chars[|chars| - (x + 1)] }
4 :
5   int i = 0
6   int j = |chars|
7
8   while i < j
9     where i + j == |chars| && i >= 0
10    where all { k in 0..i | chars[k] == chars[|chars| - (k+1)] }
11 :
12   j = j - 1
13   if chars[i] != chars[j]
14   :
15     return false
16   i = i + 1
17
18 return true

```

```

1 method isPalindrome(chars: array<int>) returns (r: bool)
2   requires chars != null
3   ensures r <=> forall x: int :: 0 <= x < chars.Length
4     ==> chars[x] == chars[chars.Length - (x + 1)]
5 {
6   var i: nat := 0;
7   var j: nat := chars.Length;
8   //
9   while i < j
10    invariant i + j == chars.Length && i >= 0
11    invariant forall k: int :: 0 <= k < i
12      ==> chars[k] == chars[chars.Length - (k + 1)]
13  {
14    j := j - 1;
15    if chars[i] != chars[j]
16    {
17      return false;
18    }
19    i := i + 1;
20  }
21  return true;
22 }

```

```

1 function firstIndexOf(int[] items, int item) -> (int r)
2   // If result is positive, element at that position must match item
3   ensures r >= 0 ==> items[r] == item
4   // If result is positive, no element at lesser position matches item
5   ensures r >= 0 ==> no { k in 0..r | items[k] == item }
6   // If result is negative, no element matches item
7   ensures r < 0 ==> no { k in 0..|items| | items[k] == item }
8 :
9   int i = 0
10  while i < |items|
11    // i is increasing and no element at greater position matches item
12    where 0 <= i && i <= |items|
13    where no { k in 0..i | items[k] == item }
14  :
15    if items[i] == item
16    :
17      return i
18    i = i + 1
19  // didn't find item in entire list
20  return -1

```

```

1 method firstIndexOf(items: array<int>, item: int) returns (r: int)
2   requires items != null
3   ensures r < items.Length
4   // If result is positive, element at that position must match item
5   ensures r >= 0 ==> items[r] == item
6   // If result is positive, no element at lesser position matches item
7   ensures r >= 0 ==> forall k: nat :: k < r ==> items[k] != item
8   // If result is negative, no element matches item
9   ensures r < 0 ==> forall k: nat :: k < items.Length
10     ==> items[k] != item
11 {
12   var i: int := 0;
13   while i < items.Length
14     // i is increasing and no element at greater position matches item
15     invariant 0 <= i <= items.Length
16     invariant forall k: nat :: k < i ==> items[k] != item
17   {
18     if items[i] == item
19     { return i; }
20     i := i + 1;
21   } // didn't find item in entire list
22   return -1;
23 }

```

```

1 function lastIndexOf(int[] items, int item) -> (int r)
2   // If result is positive, element at that position must match item
3   ensures r >= 0 ==> items[r] == item
4   // If result is positive, no element at greater position matches item
5   ensures r >= 0 ==> no { x in (r + 1)..|items| | items[x] == item }
6   // If result is negative, no element matches item
7   ensures r < 0 ==> no { x in 0..|items| | items[x] == item }
8 :
9   int i = |items|
10  while i >= 0
11    // i is decreasing and no element at greater position matches item
12    where 0 <= i && i <= |items|
13    where no { x in i..|items| | items[x] == item }
14  :
15    i = i - 1
16    if items[i] == item:
17      return i
18  // didn't find item in entire list
19  return -1

```

```

1 method lastIndexOf(items: array<int>, item: int) returns (r: int)
2   requires items != null
3   ensures r < items.Length
4   // result is positive element at that position must match item
5   ensures r >= 0 ==> items[r] == item
6   // result is positive no element at greater position matches item
7   ensures r >= 0 ==> forall x: r < x < items.Length
8     ==> items[x] != item
9   // If result is negative, no element matches item
10  ensures r < 0 ==> forall x: 0 <= x < items.Length
11    ==> items[x] != item
12 {
13   r := items.Length;
14   while r > 0
15     // no element at greater position matches item
16     invariant 0 <= r <= items.Length
17     decreases r
18     invariant forall x: r <= x < items.Length ==> items[x] != item
19   {
20     r := r - 1;
21     if items[r] == item { return; }
22   }
23   // didn't find item in entire list
24   r := -1;
25 }

```

```

1 public function maxArray(int[] items) -> (int max)
2   requires |items| > 0
3   ensures some { k in 0..|items| | max == items[k] }
4   ensures all { k in 0..|items| | max >= items[k] }
5 :
